Abstract: Pentacoordinate carbon atoms are theoretically predicted here in a ferrocene dication derivative in both staggered-
[Fe(Si$_2$C$_5$H$_4$)$_2$]$_{2+}$ (1; $C_{2v}$) and eclipsed-[Fe(Si$_2$C$_5$H$_4$)$_2$]$_{2+}$ (2; $C_{2h}$) forms for the first time. The barrier between these two ranges from -38.11 to 4.90 kJ mol$^{-1}$ at different levels. The planar tetracoordinate carbon atom in the ligand Si$_2$C$_5$H$_4$ becomes a hypervalent pentacoordinate carbon upon complexation.

Carbon showing hypervalent behavior - either penta or hexa - is rare but not very new to chemists. 1-7 Non-planar pentacoordination to carbon has already been well established in systems such as CH$_2^+$, ClI$_5$, 10 C(CH$_3$)$_5$, 11 [(Ph$_6$P$_5$)Cu]$_2^+$, 12 and Si$_2$C$_2$(H$_2$)$_2$. 13 Likewise, non-planar hexacoordination to carbon has been proven in CLi$_6$, 10,14 [(Ph$_3$P$_5$)Cu]$_6$C$_3$)$_{2+}$, 15 and C$_6$(CH$_3$)$_6$. 16,17 Carbon atom having heptavalency is theoretically predicted in trophylium tri-(Ph$_6$P$_5$)hexacoordination to carbon has already been well estab-
lished in systems such as CH$_2^+$, 1-7 C(CH$_3$)$_5$, 11 [(Ph$_6$P$_5$)Cu]$_2^+$, 12 and Si$_2$C$_2$(H$_2$)$_2$. 13 Likewise, non-planar hexacoordination to carbon has been proven in CLi$_6$, 10,14 [(Ph$_3$P$_5$)Cu]$_6$C$_3$)$_{2+}$, 15 and C$_6$(CH$_3$)$_6$. 16,17 Carbon atom hav-
ing heptavalency is theoretically predicted in trophylium tri-
cation, C$_7$H$_5$+. 18 Ferrocene, Fe($η^5$-C$_5$H$_5$)$_2$, is an eminent molecule over the last seven decades. 19-22 It opened a new avenue called organometallic chemistry, which is continuously growing since 1951. 19,23,24 Here, using Si$_2$C$_5$H$_4$ as a ligand, two ferrocene derivative dication structures are the-
oretically identified – staggered-[Fe(Si$_2$C$_5$H$_4$)$_2$]$_{2+}$ (1; $C_{2h}$) and eclipsed-[Fe(Si$_2$C$_5$H$_4$)$_2$]$_{2+}$ (2; $C_{2v}$) – that shows hyperv-
alent nature (pentacoordination) to its ligand carbon atom (see Figure 1). The latter was previously a planar tetra-
ordinate carbon (ptC) atom 25,26 in the absence of Fe$^{2+}$ ion. Both 1 and 2 exhibit two hypervalent pentacoordinate carbon atoms due to the formation of a metallocene complex.

In our earlier theoretical work, various isolomers of Si$_2$C$_5$H$_4$ have been theoretically identified and it was concluded that the molecule with a ptC atom, 2,7-
disilatricyclo[4.1.0.6.13]hept-2,4,6-trien-2,7-diy1, is the most stable structure thermodynamically. 27 The global minimum geometry for Si$_2$C$_5$H$_4$ has also been theoretically verified elsewhere through search algorithms. 28 The kinetic stability of the latter through appropriate dissociation pathways has been analyzed by us in detail recently. 29 It was proven theoretical-
ly that the global minimum isomer of Si$_2$C$_5$H$_4$ with a ptC atom is not only thermodynamically stable but also kinetically stable. 29

Considering the fact that both 1 and 2 are dications with a net charge of 2+, it was speculated that Fe is in +4 oxidation state ([Ar] 3d$^4$) as in decamethylferrocene dication. 30 However, the electronic ground states in both 1 and 2 are not triplets and they are rather singlets. Moreover, the triplets are 70.98 and 16.46 kJ mol$^{-1}$ above singlets in 1 and 2, respectively, at the ωB97X-D/6-311++G(2d,2p)-SDD (Fe) level of theory. Thus, the oxidation state of Fe in both 1 and 2 is +2 ([Ar] 3d$^6$) and the ligands (Si$_2$C$_5$H$_4$) are neutral. Overall, these complexes do follow the effective atomic number (EAN) rule (EAN = 36) and attain the electron configuration of Kr. Therefore, we believe that these complexes could effectively be identified in the laboratory sooner than later provided if Si$_2$C$_5$H$_4$ ligand could be prepared.

The C-C bond length in 1 range from 1.41 to 1.46 Å (see Figure 1 (a)) whereas in 2 it varies from 1.42 to 1.47 Å (see Figure 1 (b)). Compared to ferrocene, 44 where the mean C-C bond length is equal to 1.431 Å, these bond lengths are slightly varied, which is reasonable due to the ionic character (dication) in these complexes apart from the presence of silicon atoms. Likewise, the Fe-C bond length in 1 range from 2.08 to 2.12 Å whereas in 2 it varies from 2.07 to 2.10 Å. In ferrocene, the mean Fe-C bond length is equal to 2.059 Å and here they are slightly longer. The Si-C bond length connected to the hypervalent carbon is 2.00 Å in 1 and 1.99 Å in 2, which reflects its single bond characteristics whereas the Si-C bond on the sides are shorter with a bond length of 1.79 Å in both the cases. This shows its double bond character-

## Figure 1. Optimized structures of (a) staggered- and (b) eclipsed-[Fe(Si$_2$C$_5$H$_4$)$_2$]$_{2+}$ (Fecorange; Sibisque; Cgray; Hwhite). Bond lengths are indicated in Å. Wiberg bond indices are given in (c) and (d), respectively. Calculations are done at the ωB97X-D/6-311++G(2d,2p)-SDD (Fe) level of theory.
1. All geometry optimization and frequency calculations for 1 and 2 were carried out using 6-311++G(2d,2p) basis set.32 For Fe, Stuttgart/Dresden effective core potential of MWF10 and the corresponding atomic natural orbital basis set were used in all calculations.33 Various density functionals were used such as B3LYP,35 TPSSh,36 M06-L,37 and ωB97X-D.33 Calculations were also done with empirical dispersion corrections (D3)38 with Becke-Johnson damping (BJ).39,40 (i.e., B3LYP-D3BJ, TPSSh-D3BJ). Natural bond orbital analyses were done using ωB97X-D functional to obtain the natural atomic charges and Wiberg bond indices (WBIs).41 All calculations were carried out using the Gaussian program package.42

Both 1 and 2 contain two hypervalent pentacoordinate carbons. This could be justified with the WBIs calculated (see Figures 1 (c) and (d)) for these two structures. For 1, all WBI values for Fe-C are in the range of 0.38 to 0.40 whereas in 2 they are in the range of 0.39 to 0.40. This indicates that they are indeed single bonds. The hypervalent C-Si WBI values in 1 and 2 are 0.36 and 0.38, respectively, reflecting single bond characteristics. WBI values for all C-C bond lengths are greater than 1, which indicates resonance stabilization plus double bond characteristics. On the basis of these values, one could certainly conclude that the central carbon atoms are hypervalent (penta) in both the cases. It is emphasized here that each hypervalent carbon obeys the octet-rule as the total WBI for each hypervalent carbon is 3.48 for 1 and 3.49 for 2. However, some of the bonds (Si-C and C-Fe) are electron-deficient bonds with fewer than two electrons as mentioned elsewhere in the example of C(CH₃)₃.11 Nevertheless, with appropriate counter ions, it is likely that these new ferrocene derivatives could be isolated in the laboratory opening an avenue for hypervalent carbon chemistry.
