Abstract (~200 words)

Catalysis by late transition metal complexes is enabled by their facile reversible redox reactivity based on their partially filled d-orbitals. The realization of such redox catalysis by p-block elements is a challenging but rewarding research subject for the advancement in both fundamental main group chemistry and sustainable catalytic technology.1–6 In this context, a P(III)/P(V) redox cycle that involves pentacoordinate phosphorane is a competent manifold for applications to catalytic reactions via a formal oxidative addition/transmetalation/reductive elimination sequence. Despite the promising stoichiometric redox reactivity of pentacoordinate organophosphorus compounds,7,8 their use in catalytic processes have been primarily limited to oxygen transfer reactions that involve the interconversion between phosphines and phosphine oxides, except for relatively simple,
prototypical transformation, such as hydrogenation\textsuperscript{9} and reduction of allyl bromides.\textsuperscript{10} We report herein on the phosphine-catalyzed hydrovinylation reaction by three-component coupling of acyl fluorides, silyl enol ethers, and alkynoates. The key to the success of the reaction is the formal transmetalation between pentacoordinate P(V) species (i.e., fluorophosphorane) and a silyl enol ether, which allows for C–C bond formation between the polarity-mismatched sites. The bond formation that cannot be attained even by transition metal catalysis is accomplished by a P(III)/P(V) manifold.
Fig. 1. Phosphorus mimics transition metal behavior. a, Comparison of well-established organometallic steps for transition metals and hypothetical steps mediated by phosphorus. EWG = electron-withdrawing group.

The widespread use of transition metal complexes as catalysts stems from their facile reversible redox reactivity based on their partially filled d-orbitals. The use of p-block elements as surrogates for transition metal catalysts has also attracted considerable interest in terms of both the fundamental aspects of main group elements in uncommon oxidation states and concerns related to the shortage of some metallic elements.\(^1\)\(^–\)\(^6\) The P(III)/P(V) redox cycle is a competent main group-based manifold for applications in catalytic reactions (Fig. 1a). However, the reported examples of catalytic reactions based on the P(III)/P(V) couple are primarily limited to oxygen...
transfer reactions mediated by the reversible interconversion of phosphine/phosphine oxide (i.e., P(III)/O=P(V) cycle).\textsuperscript{4,11} In a P(III)/O=P(V) cycle, the catalyst regeneration step (O=P(V) to P(III)) is irrelevant to the product formation, and a sacrificial reducing agent is essential. It would appear that the P(III)/P(V) manifold could be used for a wider range of catalytic reactions in view of a number of studies on the stoichiometric redox reactivity of organophosphorus compounds in mediating formal oxidative addition or reductive elimination processes through a pentacoordinate phosphorane intermediate as a P(V) species.\textsuperscript{1,7,8} However, examples reported thus far are limited to relatively simple, prototypical transformations, including hydrogenation,\textsuperscript{9} reduction of allyl bromides,\textsuperscript{10} and acylfluorination of alkynes.\textsuperscript{12} Herein, we report on extending P(III)/P(V) catalyst system to a phosphine-catalyzed formal hydrovinylation reaction by the three-component coupling of acyl fluorides, silyl enol ethers, and alkynoates.

The 1,3-diene motif is frequently found in complex natural products and biologically active molecules,\textsuperscript{13} and also serve as a versatile synthetic precursor for a variety of important organic transformations.\textsuperscript{14,15} Consequently, intense efforts have been expended to development of efficient and practical methods for producing these valuable structural motifs.\textsuperscript{16} Among the methods reported to date, the catalytic hydrovinylation of alkynes is a straightforward approach and has been a subject of considerable research interest.\textsuperscript{17,18} The hydrovinylation of alkynes using enol derivatives is of particular interest because the resulting conjugate dienolate derivatives can be used in a variety of useful synthetic transformations.\textsuperscript{19,20} However, despite the potential synthetic impact, the
catalytic hydrovinylation of alkynes using enol derivatives has not been accomplished, except for the following two examples. Loh\textsuperscript{21} and Zhang\textsuperscript{22} independently reported that enol derivatives bearing a directing group on the oxygen atom can add across alkynes via transition metal-catalyzed vinylic C–H bond activation (Fig. 1b, left). In these reactions, a new C–C bond can be forged between the nucleophilic carbon of an enol and the electrophilic β-carbon of an alkyne when electron-deficient alkynes are used (Michael-type addition). The three component reaction reported herein involves the alkenylation of a vinylic C–H bond and the acylation of an Si–O bond of silyl enol ethers occur in one reaction sequence (Fig. 1b, right). Notably, the C–C bond formation involves umpolung, which allows for connection between polarity mismatched sites to afford an anti-Michael-type adduct. This regioselectivity is complementary to that observed in the transition metal-catalyzed hydrovinylation of alkynes using enol derivatives.\textsuperscript{21,22}

Quite recently, we reported on the phosphine-catalyzed intermolecular addition of acyl fluorides across triple bonds in electron-deficient alkynes (Fig. 2a). In this reaction, a pentacoordinate fluorophosphorane 1 is involved as the key intermediate, and a C–F bond is formed via ligand coupling (LC) on 1, an alternative to reductive elimination on transition metal complexes. We envisioned that a three-component coupling would be possible if ligand metathesis (LM) between a fluoride on the phosphorus center of 1 and an organometallic nucleophile were to take
place, in a manner similar to the transmetalation reaction on transition metal complexes (Fig. 2b).

Silyl enol ethers were chosen as a feasible nucleophile because they can be readily prepared from a range of carbonyl compounds by reliable protocols and exhibit temperate reactivity as an enolate equivalent amenable to various catalysis manifolds. We anticipated that ligand metathesis would generate the phosphorane 2, which would eventually lead to the formation of densely functionalized alkene 3 via ligand coupling. The three-component coupling of benzoyl fluoride (4a), silyl enol ether 5a, and methyl phenylpropionate (6a) was initially examined. Although, the expected three-component coupling product 3aaa was not observed, the 1,3-diene 7aaa, which can be viewed as a formal hydrovinylatation product, was obtained in 38% yield (E:Z = 36:64). X-ray crystallographic analysis unambiguously determined that the alkenylation of a vinylic C–H bond and O-acylation of silyl enol ether simultaneously occurred with C–C bond formation between the polarity mismatched sites. Intrigued by the unusual bond connection mode and the rapid assembly of elaborate 1,3-dienes from simple building blocks, we embarked on a study of this synthetic transformation in more detail. Increasing the catalyst loading to 30 mol% improved the yield of 7aaa to 43% (Fig. 2c, entry 1). Since we identified the 1,3-diketone 8aa and the vinyl ester 9aa as major byproducts (see Fig. 4a-(i) for the structure of 8aa and 9aa), which were formed by the direct addition of 5a to 4a, the slow addition of 4a was examined. The dropwise addition of 4a (7 μL/h, 2.0 equiv) to a mixture of 5a (2.0 equiv), 6a and PCy3 afforded the 1,3-diene 7aaa in 84% isolated yield (E:Z = 37:63) (entry 2). Alternatively, increasing the amount of 4a and 5a (3.0 equiv each)
also improved the yield of 1,3-diene 7aaa without the dropwise addition of 4a (entry 3). Other phosphines, such as P^tBu3, PPhMe2 and PPh3, and amines (DMAP and DABCO) failed to promote this three-component coupling.
Fig. 3. Scope of the phosphine-catalyzed three-component coupling.
a, Scope of the phosphine-catalyzed three-component coupling. Reaction conditions: dropwise addition of 4a (0.40 mmol) at 7 μL/h to a mixture of 5a (0.40 mmol), 6a (0.20 mmol), and PCy₃ (0.06 mmol) in toluene (1.0 mL), then at room temperature for 14 h. Yields of isolated products are shown. The (Z,E):(Z,Z) ratios that were determined by ¹H NMR analysis are shown in parentheses.

b, 4a (0.60 mmol), 5a (0.60 mmol), 6a (0.20 mmol), PCy₃ (0.06 mmol), and toluene (1.0 mL) at room temperature for 20 h. c, 4a (16.5 mmol), 5a (16.5 mmol), 6a (5.50 mmol), PCy₃ (1.65 mmol), and toluene (30 mL) at room temperature for 20 h. 1.62 g of product was obtained. b, Transformations of the three-component coupling product 7aba. Selectfluor = 1-chloromethyl-4-fluoro-1,4-diazeniabicyclo[2.2.2]octane bis(tetrafluoroborate). TCNE = tetracyanoethylene. PTAD = 4-phenyl-1,2,4-triazoline-3,5-dione.

With the optimized reaction conditions in hand, we subsequently examined the scope of the three-component coupling (Fig. 3a). The silyl enol ether 5b, which was prepared from acetophenone, participated in this reaction to produce 7aba, in which the C–H bond cis to the siloxy group in 5b was exclusively alkenylated. Regarding the stereochemistry of an alkene moiety derived from 6a, the E configuration was dominated [(Z,E):(Z,Z) = 18:82]. The structure of (Z,Z)-7aba was confirmed by a single-crystal X-ray analysis. Silyl enol ethers bearing methyl (5c), methoxy (5d), and cyano (5e) groups readily participated in this reaction. Halogen groups such as chloro (5f) and bromo (5g) were compatible, allowing the resulting 1,3-diene to be amenable to
further structural elaboration via common C–X bond functionalization reactions. Substrates containing heteroarenes such as furan (5h) and thiophene (5i) also successfully underwent the three-component coupling. The silyl enol ether 5j, which was prepared from acetone, participated in this reaction to produce 7aja with a high stereoselectivity \[(Z,E):(Z,Z) = 9:91\]. Five-membered (5k), six-membered (5l, 5m, 5n), and seven-membered (5o, 5p) cyclic silyl enol ethers all reacted to afford the corresponding 1,3-diene derivative. Aromatic alkynoates bearing methyl (6b), methoxy (6c), fluoro (6d), and thienyl groups (6e, 6f) were also viable substrates for this three-component coupling with high Z-selectivity. The three-component coupling can also be applied successfully to non-aromatic alkynoates bearing cyclopropyl (6g) and n-pentyl (6h) groups. This three-component coupling also proceeded when alkynoates bearing a different ester moiety such as ethyl (6i), t-butyl (6j), and allyl (6k) esters were used. It was also possible to use several acyl fluorides, such as those bearing cyano (4b), chloro (4c), iodo (4d), and π-extended aryl (4e) groups to afford the corresponding products 7bba–7eba. The structural elaboration of pharmaceuticals containing a carboxylic acid functionality into the corresponding 1,3-dienes is possible through acid fluoride formation followed by the three-component coupling (i.e., the conversion of probenecid into 7fba).

Containing both vinyl ester and 1,3-diene moieties, the three-component coupling products can serve as valuable synthetic intermediates (Fig. 3b). For example, the vinyl ester moiety could be selectively converted into the corresponding fluorinated 1,4-dicarbonyl product 11aba by treating (Z,Z)-7aba with Selectfluor \(^{23}\). The vinyl ester moiety in (Z,Z)-7aba could also be arylated by
Ni-catalyzed Suzuki–Miyaura coupling via C(sp\(^2\))–O activation.\(^{24}\) The Diels–Alder reaction of (Z,Z)-7aba with the tetracyanoethylene (TCNE) and 4-phenyl-1,2,4-triazoline-3,5-dione (PTAD) afforded the densely functionalized cyclohexene 13aba and 14aba, respectively, with retention of the relative stereochemistry.
Fig 4. Mechanistic studies. a, Mechanistic studies involving control experiments, deuterium-labeled experiments and isomerization experiments. b, Proposed mechanism by P(III)/P(V) catalysis. c, Computed energy profile of the three-component coupling from a fluorophosphorane intermediate. Calculations were performed at the PCM (toluene)-M06-2X/6-31+G(d,p) level of theory. d, Experimental observation of ligand metathesis.

To gain insights into the reaction mechanism, several control experiments were performed (Fig. 4a). In this three-component coupling between 4a, 5a, and 6a, 1,3-diketone 8aa and vinyl ester 9aa were observed as byproducts, which are likely formed by the direct reaction between 4a and 5a. To examine the involvement of 8aa and 9aa as a viable intermediate in this
three-component coupling, the PCy3-catalyzed reaction of 8aa (or 9aa) with 6a was conducted. However, the expected 1,3-diene 7aaa was not formed, excluding the intermediacy of 8aa and 9aa (Fig. 4a-(i)). Monofluoroalkene 10ba, which can also be formed by phosphine-catalyzed carbofluorination between acyl fluoride 4b and alkynoate 6a, is a potential intermediate in this three-component coupling. However, the desired product 7bba was not formed from 10ba under these reaction conditions, ruling out the involvement of 10ba (Fig. 4a-(ii)). Deuterium labeling experiments were performed to investigate the origin of the vinylic hydrogen atoms (Fig. 4a-(iii)).

The three-component coupling of 4a, 6a, and the deuterium labeled silyl enol ether 5b-d2 (97%D) afforded 7aba-d2 under the standard reaction conditions, with deuterium atoms incorporated at the 4-position (50%D), in addition to the 2-position (96%D). Although the deuterium content at the 4-position was 50%, the majority of the cleaved deuterium atoms are incorporated into the product. When this labeling experiment was carried out in the presence of 2.0 equiv of deuterium oxide (D2O), the deuterium content of 7aba-d2 at the 4-position increased to 93%. This result indicates that the decrease in the deuterium content at the 4-position is due to exchange with trace amounts of water that are present in the system.25,26 Regarding the stereochemistry of the alkene moiety derived from the alkyne, (Z)-isomers were predominantly formed, even though the corresponding (E)-isomers were thermodynamically more stable (For example, (Z,E)-7aba is more stable than (Z,Z)-7aba by 1.8 kcal/mol). In fact, the exposure of the geometrically pure (Z,Z)-7aba to the catalytic conditions did not induce any isomerization, indicating that the (Z,Z)-isomer is a
kinetically favored product (Fig. 4a-(iv)). Regarding the stereochemistry of the alkene moiety derived from the silyl enol ethers, the vinylic C–H bond that is cis to the siloxy group is exclusively alkenylated. However, when the (Z)-silyl enol ether 5q was used as a substrate, 1,3-dienes with a (Z)-geometry with respect to the enol moiety was formed exclusively. The structure of (Z,Z)-7aq was confirmed by a single-crystal X-ray analysis. These results indicate that this three-component coupling involves a stereoconvergent process with respect to the geometry of the enol moiety (Fig. 4a-(v)).

A proposed reaction pathway is depicted in Fig. 4b. The catalytic reaction starts with the addition of PR₃ to an alkynoate to generate the carbanion IM0, which subsequently undergoes nucleophilic acyl substitution with an acyl fluoride to form the fluorophosphorane 1. Ligand metathesis between 1 and the silyl enol ether driven by the formation of a stable Si–F bond proceeds to afford alkoxyphosphorane 2, in preference to the ligand coupling of 1, to form a C–F bond. The [3,3]-sigmatropic rearrangement of 2 forges a new carbon–carbon bond between the α-carbon of the silyl enol ether and α-carbon of an electron-deficient alkyne to afford the phosphonium ylide IM3. The ylide moiety in IM3 abstracts the α-hydrogen derived from the silyl enol ether to generate the enolate IM4. This [1,3]-proton transfer could be mediated by a trace amount of endogenous water in the system, which also explains the decrease in the deuterium content at the 4-position of the product in the labelling experiment (Fig. 4a-(iii)). The enolate moiety in IM4 subsequently adds to the carbonyl group derived from the acyl fluoride, and the
resulting alkoxide anion attacks the phosphorus center to generate the bicyclic phosphorane intermediate IM5. The intermediate IM5 then collapses to the final 1,3-diene 7 with the regeneration of PR3. The (Z)-geometry of the enolate moiety in IM4 is essential for the cyclization to occur to form IM5, which is consistent with the fact that the both (E) and (Z)-enolates converge into 1,3-dienes with a (Z)-enol moiety.

Density functional theory (DFT) calculations were carried out using PMe3 as a model catalyst in order to examine the feasibility of the proposed mechanism after the formation of 112 (Fig. 4c).27 Ligand metathesis between IM1 and the silyl enol ether is endergonic by 1.2 kcal/mol to generate phosphorane IM2, which undergoes the [3,3]-sigmatropic rearrangement to form the phosphonium ylide IM3′ with a reasonable activation barrier (ΔG‡ = 6.9 kcal/mol). An alternative pathway involving the addition of enolate to vinylphosphonium28 via an acyclic open transition state (i.e., TS2) was found to be energetically less favored (ΔG‡ = 12.1 kcal/mol). The subsequent [1,3]-proton transfer step (i.e., IM3’ → IM4’) requires a high energy transition state (TS4, ΔG‡ = 28.1 kcal/mol) when proton migrates directly. The activation barrier is significantly lowered when water is considered to be the proton shuttle (TS3, ΔG‡ = 14.2 kcal/mol), a finding that is consistent with the results of the labelling experiment (Fig. 4a-(iii)). DFT calculations revealed that the intermediate IM4′ behaves as a short-lived transient intermediate and is converted to bicyclic phosphorane IM5′ with no appreciable energetic barrier. The regeneration of the phosphine catalyst was found to proceed through two steps via IM6 with an activation barrier of 20.3 kcal/mol, which
is reasonable for reactions that proceed at room temperature. The energy diagram also indicates that the process from IM6 to the product is irreversible ($\Delta G^\ddagger$ for the product to IM6: 32.6 kcal/mol), which is consistent with the geometrical stability of (Z,Z)-7aba under the catalytic conditions (Fig. 4a-(iv)).

To further verify the intermediacy of alkoxyphosphorane, a stoichiometric reaction between isolable fluorophosphorane 15 and silyl alkoxide was performed (Fig. 4d). The ligand metathesis proceeded immediately, quantitatively giving alkoxyphosphorane 16, which has a pentacoordinate geometry determined by VT-NMR experiments (Fig. S3).

In conclusion, we report on the phosphine-catalyzed three-component coupling of acyl fluorides, silyl enol ethers, and alkynes, which provides straightforward access to a variety of densely functionalized 1,3-dienes. This reaction operates under mild conditions and in the absence of transition metals, therefore permitting a wide functional group tolerance. The key feature of this reaction is ligand metathesis on the fluorophosphorane platform, which allows for the bond formation between polarity mismatched sites to form anti-Michael-type adducts. This study demonstrates the potential utility of a P(III)/P(V) manifold as a viable alternative to transition metal-mediated catalytic cycles consisting of oxidative addition, transmetalation and reductive elimination. Further studies directed at the development of new reactions using the fluorophosphorane platform are currently underway in our laboratory.

Author contribution
H.F., M.K., and T.K. performed and analysed the experiments. H.F., M.K., and M.T. designed the experiments. H.F. and M.T. prepared the manuscript.
