## Abstract

We report the direct light activation of ethynylbenziodoxolone (EBX) reagents for the oxyalkynylation of aryl- and amino-cyclopropanes as well as styrenes. Irradiation with visible light at 440 nm promoted the reaction without the need of a photocatalyst. By the choice of the aryl group on the cyclopropane, it was possible to completely switch the outcome of the reaction from the oxyalkynylation of the C-C bond to the alkylation of the C-H bond. This effect has been speculatively attributed to the conformational control induced by the aryl group on the cyclopropane ring

## Introduction

Hypervalent iodine reagents are now well-established for the functionalization of nucleophiles under mild conditions due to their unique reactivity.<sup>1</sup> More recently, they have been also successful in the functionalization of radicals. In particular, ethynylbenziodoxolone (EBX) reagents have emerged as excellent radical traps, enabling the synthesis of alkynes otherwise difficult to access (Scheme 1A).<sup>2</sup> Efficient access toward structurally diverse alkynes is urgently needed, due to their numerous applications in synthetic and medicinal chemistry, chemical biology and organic materials.<sup>3</sup> The combination of visible-light photocatalysis and EBX reagents has been especially successful, allowing new processes, such as decarboxylative<sup>4</sup> or deoxygenative alkynylations,<sup>5</sup> as well as alkene<sup>6</sup> and C-H functionalization.<sup>7</sup>

In contrast, the direct alkylation of inert C-C bonds is more challenging. The use of the ring strain of cyclopropanes is well-established in synthetic chemistry to enable C-C bond cleavage. First applied to more reactive Donor-Acceptor systems,<sup>8</sup> less reactive Donor-only arylcyclopropanes could be also recently functionalized through oxidative activation to give radical cations (Scheme 1B).<sup>9</sup> Photocatalytic methods have further led to new multi-functionalization reactions.<sup>10</sup> However, concerning alkylation, success has been limited for a long time to cyclopropanols, giving access only to ketones as products.<sup>11</sup> In 2021, Chen and co-workers developed the first photocatalyzed oxyalkynylation of the C-C bond of aminocyclopropanes (Scheme 1C1).<sup>12</sup> During preparation of this manuscript, Studer and co-workers reported in January 2022 the first addition of EBX reagents to the C-C bond of arylcyclopropanes (Scheme 1C2).<sup>13</sup> Both methods required a careful optimization of additives and photocatalyst for success.

Our group recently discovered the direct visible light activation of aryl-substituted EBX reagents.<sup>14</sup> The generated excited species could be used for the oxidative alkylation of several functional groups and alkenes. A key advantage of this approach is the simplicity of the procedure, requiring only the irradiation of a mixture of substrates and EBX reagents without the need for fine-tuned photocatalysts and additives. We wondered therefore if this approach would be also successful in the case of the oxyalkynylation of the C-C bond of aryl cyclopropanes.

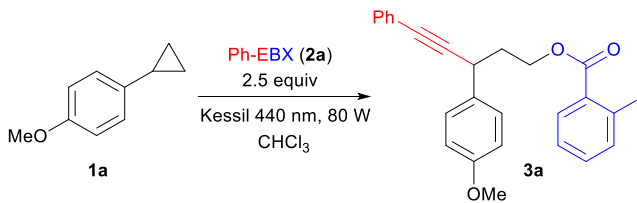

Although the direct light-mediated oxidation of arylcyclopropanes has been reported with nitrogen-based and chloride radicals,<sup>15</sup> alkylation could not be achieved so far in absence of a photocatalyst.

Herein, we report the first ring-opening oxyalkynylation of aryl cyclopropanes through the direct photoexcitation of EBX reagents (Scheme 1D). The 1,3-oxyalkynylation products were obtained with full regioselectivity, in yields comparable to those of photocatalytic methods. The same conditions were also used for the 1,3-oxyalkynylation of aminocyclopropanes and the 1,2-oxyalkynylation of styrenes. In addition, the reaction outcome could be changed from C-C to C-H alkylation in dependence of the aryl group on the cyclopropane.

## Results and discussion

To start our studies, we choose *para*-methoxybenzene substituted cyclopropane **1a**, as it can be oxidized at a relatively low potential ( $E_{1/2} = +1.35$  V).<sup>15b</sup> As we had estimated the oxidation potential of photoexcited Ph-EBX\* (**2a\***) to be +1.8 V,<sup>14</sup> the generation of a radical cation should be possible. Indeed, efficient oxyalkynylation to give **3a** was observed (Table 1). The best results were obtained using chloroform as solvent and 2.5 equivalents of **2a**. Under these conditions, **3a** was isolated in 68% yield. The only observed side product was double addition of 2-iodobenzoate in 10% yield, probably resulting from over-oxidation of the benzylic radical to the cation. To obtain reproducible results, thorough degassing of the reaction mixture and purifying Ph-EBX (**2a**) by recrystallization were required (See Supporting Information for details). Product **3a** was also obtained in other chlorinated solvents, but only in moderate yields (entries 2-3). Only very low yields were observed in other solvents (entry 4). Irradiation at 467 nm was less efficient (entry 5). No product was obtained when using a blue LED strip (entry 6). This confirmed that strong irradiation is needed to activate directly aryl EBX reagents. During completion of our work, Zuo and Studer indeed reported that a photocatalyst and BI-OAc as additive are needed with blue LED strips to obtain **3a** in 67% isolated yield.<sup>13</sup> A lower yield was obtained with two equivalents **2a**, and using three equivalents did not improve the yield (entries 7 and 8). This is in agreement with what we observed in our previous work,<sup>14</sup> indicating that one equivalent of **2a** is probably acting as oxidant, and a second one as alkylation reagent. In contrast to Zuo and Studer's work, no additive was needed in the reaction and adding 50% of BI-OAc gave no improvement (entry 9). Finally, no product was obtained when heating the reaction mixture at 50 °C in the dark (entry 10).

Reaction Conditions: 0.2 mmol **1a** (1 equiv), 0.5 mmol **2** (2.5 equiv), two Kessil lamps (440 nm, 2x40 W), in 2 mL CHCl<sub>3</sub>. <sup>31</sup>H NMR Yield and conversion were determined with CH<sub>2</sub>Br<sub>2</sub> as an internal standard. Isolated yield after chromatography is given in brackets.

With optimized conditions in hand, we studied first the scope of arylcyclopropanes (Scheme 2A). As expected, electron-rich substituents were required to promote the reaction: oxyalkynylation products **3a-c** bearing a methoxy or an ethoxy substituent were obtained in 51-68% yield, whereas a *tert*-butyl substituent gave **3d** in only 15% yield and no product was obtained for an unsubstituted benzene ring (**3e**). For **3a** and **3b**, the yields obtained were comparable or slightly superior to the photocatalytic method developed by Zuo and Studer.<sup>13</sup> However, the photocatalyst approach is superior for less electron-rich substrates not accessible via direct photoexcitation of EBXs: Products **3d** and **3e** were obtained in 52% and 40% respectively using an acridinium dye as photocatalyst. A methyl group in *ortho* position was well tolerated to give product **3f**. However, no product **3g** was obtained with two *ortho* methyl groups. Surprisingly, C-H alkylation product **4a** was isolated in 85% yield instead. In presence of a methoxy group, an electron-deficient fluoro substituent was tolerated to give product **3h** in 46% yield. Starting from  $\beta$ -substituted cyclopropanes, products **3i** and **3j** were obtained in 70% and 54% yield with selective attack of the iodobenzoate at the most encumbered position. We then examined the scope of EBX reagents, considering that only aryl-substituted EBXs are photoactive (Scheme 2B).<sup>14</sup> A tolyl-substituted EBX gave **3k** in 45% yield. Introduction of a *para*-trifluoromethyl or a chloro group on the aryl ring of the alkyne led to **3l** and **3m** in 63% yield. Fluoro substituents were also tolerated, but gave only moderate yields of **3n** and **3o**. These results contrasted with our previous work where only Ph- and tolyl-EBX gave useful yields of products.<sup>14</sup>

**Scheme 2** Scope of the oxyalkynylation of arylcyclopropanes. Reaction Conditions: 0.2 mmol **1a** (1 equiv), 0.5 mmol **2** (2.5 equiv), two Kessil lamps (440 nm, 2x40 W), in 2 mL CHCl<sub>3</sub>. Isolated yield after column chromatography is given. <sup>a</sup>Yield reported in Ref. 13 using 4-CzIPN as photocatalyst and BI-OAc as additive. <sup>b</sup>Yield using Ph-Acr-MesBF<sub>4</sub> as photocatalyst.

Finally, an advantage of EBXs is that the properties can be finely tuned by modification of the 2-iodobenzoic acid core of the reagent. For example the yield of transfer of the 3-F-benzene substituted alkyne could be increased from 27 to 51% by introducing a methyl group *para* to the carboxylic acid (product **3p**). A dimethoxy-substituted reagent could also be used to give **3q** in 30% yield.

Our main goal was the oxyalkynylation of the C-C bond of arylcyclopropanes. However, the same conditions can be also applied to the oxyalkynylation of aminocyclopropane **5a** giving products **6a** and **6b** in 53% and 51% yield (Scheme 3A). As reported by Chen for the photocatalytic reaction,<sup>12</sup> a complete inversion of the regioselectivity can be observed in this case. This is probably due to the lower stability of the radical cation, leading to ring-opening prior to attack of the nucleophile. The oxyalkynylation is not limited to  $\sigma$ -C-C bonds. Indeed, electron-rich styrene derivatives **7a-c** could be converted to products **8a-c** in 44-56% yield with complete regioselectivity via 1,2-oxyalkynylation of the  $\pi$  bond (Scheme 3B). In this case, the same regioselectivity is observed as for enamides.<sup>6b</sup>

Finally, we turned back to the intriguing C-H alkylation observed in the case of arylcyclopropane **1g**. In fact, 1,1-arylalkynyl cyclopropanes are useful building blocks in synthetic and medicinal chemistry.<sup>16</sup> They have never been accessed via C-H alkylation, which has been realized mostly on unsubstituted positions using directing group mediated transition metal

catalysis.<sup>17</sup> We were pleased to see that the Ph-EBX (**2a**) mediated alkylation of **1g** was surprisingly efficient, with 83% product **4a** isolated after 7 h of irradiation with only 1.5 equivalents of **2a** (Scheme 3C). The reaction was easily scalable and **4a** was obtained in 92% on a 2 mmol scale. The transformation was also successful with functionalized EBX reagents. Alkyl substituents in *para* position on the benzene ring gave products **4b** and **4c** in 65% and 40% yield. A trifluoromethyl group and halogens were well tolerated at this position, giving products **4d-g** in 70-81% yield. Finally, products **4h** and **4i**, bearing a *meta* fluoro and an *ortho* bromo group respectively, were obtained in 61% and 54% yield.

Based on our experimental results and our previous studies,<sup>14</sup> a highly speculative reaction mechanism can be proposed (Scheme 4A). Direct light activation of Ph-EBX (**2a**) would lead to the highly oxidizing species **2a\***. Single electron transfer from arylcyclopropane **1** would give then radical anion **I** and radical cation **II**. In a previous work, we showed by computation that **I** was relatively stable to monomolecular decomposition.<sup>18</sup> The major side product observed in the photoactivation of **2a** is diyne **9**, probably formed in either of two bimolecular pathway: Reaction with another molecule of **I** to give **9** and 2 equivalents of 2-iodobenzoate (**10**), or with **2a** to give **9**, **10** and radical **III**.

### A 1,3-Oxyalkynylation of aminocyclopropanes

### B 1,2-Oxyalkynylation of styrenes

### C C-H alkynylation

**Scheme 3** 1,3-Oxyalkynylation of aminocyclopropanes (A), 1,2-oxyalkynylation of styrene derivatives (B) and C-H alkynylation of arylcyclopropanes (C). Isolated yields on 0.2 mmol scale are given, see Supporting Information for detailed experimental procedures. <sup>a</sup>Isolated yield on a 2 mmol scale.

From radical cation **II**, two pathways can be considered. Ring opening with benzoate **10** to give the more stable radical **IV**, followed by reaction with **2a** (or **I**) would lead to the oxyalkynylation product **3** (pathway **a**). Deprotonation with benzoate **10** would give radical **V**, which would be then alkynylated by either **2a** or **I** resulting in the formation of **4** (pathway **b**). In general, we would favour alkynylation with **2a**, as it would be present in higher concentration, but an involvement of **I** cannot be excluded, especially in the case of C-H alkynylation, which is surprisingly efficient. For C-H alkynylation, a radical chain mechanism involving radical **III** should also be considered. In fact, H abstraction from **1** by **III** would give directly radical **V**. However, we think that this mechanism may be less probable, as no alkynylation was observed with arylcyclopropanes lacking the methoxy group such as **1k**, showing that oxidation of the substrate is probably needed for the reaction to occur. Furthermore, direct HAT on cyclopropanes is generally difficult, due to the stronger C-H bond/lower stability of the radical.<sup>19</sup>

A striking result of our studies was the complete switch of chemoselectivity when introducing a second *ortho* methyl group on the arene ring. A tentative explanation may be found in the conformational analysis of the cyclopropane (Scheme 4B).

It is well-known that aryl cyclopropanes favour a bisected conformation to enable overlap between the  $\pi$ -Walsh orbitals and the  $\pi^*$  of the benzene ring.<sup>20</sup> Another effect of this interaction is also the weakening of the C-C bond and favour ring-opening. With one *ortho* group, a low energy bisected conformer is still available. However, when a second *ortho* group is present, strong steric interactions with the cyclopropane cannot be avoided anymore. Therefore, the usually less favoured perpendicular conformation becomes lower in energy. In this conformation, there is nearly no effect of the benzene ring on the strength of the C-C bonds. In contrast, one may envision a weakening interaction between the  $\pi$  system of the benzene and the  $\sigma^*$  orbital of the C-H bond, favouring deprotonation/H abstraction. Of course, care has to be taken with this simple conformational analysis of the starting material, and future studies will focus on computations involving radical cation **II** and the transition states of the proposed pathways **a** and **b**.

## Conclusions

In summary, we have reported a light-mediated oxyalkynylation of the C-C bond of arylcyclopropanes via the direct photoactivation of aryl-EBX reagents with visible light. In contrast to previous works, neither photocatalysts nor additive

were needed. In addition, we discovered a complete switch of the reaction outcome from C-C to C-H alkynylation when using aryl cyclopropanes bearing two *ortho* substituents on the benzene ring. We tentatively attributed this effect to the conformational constraints induced by the aryl ring, and we think this result will pave the way for the development of new selective transformations of cyclopropanes.

## General Methods

For quantitative flash chromatography, distilled technical grade solvents were used. THF, Et<sub>2</sub>O, toluene, hexane and CH<sub>2</sub>Cl<sub>2</sub> were dried by passage over activated alumina under nitrogen atmosphere (H<sub>2</sub>O content < 7 ppm, Karl-Fischer titration). All chemicals were purchased and used as received unless stated otherwise. Chromatographic purification was performed as flash chromatography using Macherey-Nagel silica 40-63, 60 Å, using the solvents indicated as eluent with 0.1-0.5 bar pressure. TLC was performed on Merck silica gel 60 F254 TLC plastic or aluminium plates and visualized with UV light, permanganate stain. Melting points were measured on a calibrated Büchi B-540 melting point apparatus using open glass capillaries. <sup>1</sup>H-NMR spectra were recorded at room temperature on a Bruker DPX-400 400 MHz spectrometer in CDCl<sub>3</sub>, Acetone-*d*<sub>6</sub>, CD<sub>3</sub>CN or CD<sub>3</sub>OD, all signals are reported in ppm with the internal chloroform signal at 7.26 ppm, the internal acetone signal at 2.09 ppm, the internal acetonitrile signal at 1.94 ppm and the internal methanol signal at 3.34 ppm as standard. The data is being reported as (s = singlet, d = doublet, t = triplet, q = quadruplet, p = quintet, m = multiplet or unresolved, br = broad signal, integration, coupling constant(s) in Hz, interpretation). <sup>13</sup>C-NMR spectra were recorded with 1H-decoupling on a Bruker DPX-400 101 MHz spectrometer in CDCl<sub>3</sub>, Acetone-*d*<sub>6</sub>, CD<sub>3</sub>CN or CD<sub>3</sub>OD, all signals are reported in ppm with the internal chloroform signal at 77.0 ppm, Acetone-*d*<sub>6</sub> signal at 29.8 ppm, CD<sub>3</sub>CN signal at 1.3 ppm or CD<sub>3</sub>OD signal at 49.0 ppm as standard. Infrared spectra were recorded on a JASCO FT-IR B4100 or a Bruker Alpha-P spectrophotometer with an ATR device and a ZnSe prism and are reported as cm<sup>-1</sup> (w = weak, m = medium, s = strong). High resolution mass spectrometric measurements were performed by the mass spectrometry service of ISIC at the EPFL on a MICROMASS (ESI) Q-TOF Ultima API. HPLC measurements were done on a Agilent 1260 Infinity autosampler using a CHIRALPAK IA, IB, IC or IF column from DAICEL Chemical. The specific solvents and concentrations (in g/100 mL) are indicated.

All photocatalyzed reactions were carried out in oven dried glassware and under inert atmosphere (freeze pump thaw solvent stored on molecular sieves and under argon for maximum one week) unless specified otherwise. They were placed on a stirring plate with Kessil lamps (440 nm, 40 W) irradiating from both sides (the hood was free and coated with aluminum foil for personal protection). The distance between the Kessil lamps and the vials was approximately 10 cm. Long irradiation resulted in temperature increasing up to 50 °C during overnight reactions unless a fan was used in which case the temperature raised to 30-35°C.

### General procedure A: Synthesis of aryl cyclopropanes

To a solution of aryl bromide (5.00 mmol, 1.00 equiv) in 15:1 toluene:water (32 mL) was added potassium phosphate tribasic potassium (4.78 g, 22.5 mmol, 4.50 equiv), cyclopropylboronic acid (644 mg, 7.50 mmol, 1.50 equiv), 0.5 ml Tricyclohexylphosphine (1M solution in toluene) and palladium(II) diacetate (56.1 mg, 250  $\mu$ mol, 0.0500 equiv). The resulting mixture was heated to 110 °C. After 12 hours, the reaction mixture was cooled to room temperature, diluted with DCM (100 mL) and washed with water (100 mL). The aqueous layer was extracted with DCM (3  $\times$  100 mL). The combined organic layers were washed with brine (50 mL), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated under reduced pressure. The crude mixture was purified by column chromatography on Biotage (Büchi flashpure cartridge 40 g, gradient of pentane: ethyl acetate from 99:1 to 95:5). to obtain the product.

### 1-Cyclopropyl-4-methoxybenzene (**1a**)

## Optimization

In a 12\*75 mm Borosilicate glass tube, **PhEBX 2a** was added. The tube was then closed with a rubber septum and sealed off with parafilm. Three cycles of evacuate-refill with nitrogen were performed to remove O<sub>2</sub> and CHCl<sub>3</sub> (0.1M) was added, followed by the addition of **1a**. The reaction mixture was stirred at room temperature with Kessil lamps (440 nm). It should be noted that chloroform can be used from commercially sealed-cap bottle under inert atmosphere or it is recommended to conduct three cycles of Freeze-Pump-Thaw for other sources of chloroform before use. The reaction was monitored by NMR with CH<sub>2</sub>Br<sub>2</sub> as internal standard. NMR yield was determined by integration of ArCH NMR of products.

## Synthesis of alkynylated products

### General Procedure B (GP B):

In a 12\*75 mm Borosilicate glass tube, aryl ethynyl benziodoxolone (0.5 mmol, 2.5 equiv) was added. The tube was then closed with a rubber septum and sealed off with parafilm. Three cycle of evacuate-refill with nitrogen were performed to remove O<sub>2</sub> and CHCl<sub>3</sub> (2.0 mL, 0.1M) was added, followed by the addition of starting material (0.2 mmol). The reaction mixture was stirred at room temperature with Kessil lamps (440 nm). It should be noted that chloroform can be used from commercially sealed-cap bottle under inert atmosphere or it is recommended to conduct three cycle of Freeze-Pump-Thaw for other sources of chloroform before use. The reaction was monitored by NMR with CH<sub>2</sub>Br<sub>2</sub> as internal standard. Upon completion by either full conversion of starting material or hypervalent iodine reagents, the mixture was concentrated in vacuo and purified by on Biotage (Büchi flashpure cartridge 25 g) to obtained the product.
