properties, and lipidic diterpenoid constituents, such as carnosol, are known as characteristic components to exhibit strong antioxidant activity. This study investigates the effect of thiol compounds on the antioxidant properties of diterpenoid polyphenols. The results concerning the antioxidant activity of polyphenols in the presence of thiol showed that two polyphenols, namely carnosol and isorosmanol, enhanced antioxidant capacity against the radical-induced oxidation of lipids. Further examination of the mechanism revealed that both polyphenols exhibit excellent catalytic antioxidant activity by using the thiol group as a reduction source. Using density functional theory calculations, we attempted to explain why only these two polyphenols exhibit catalytic antioxidant properties. The calculation results and the assumed reaction mechanism suggested that the orthoquinones produced in the antioxidant reactions of carnosol and isorosmanol are more unstable than the others, and that the regioselectivity of their reactions with thiols contributes to their catalytic antioxidant properties.

KEYWORDS: *Carnosol, Isorosmanol, Catalytic Antioxidant, Rosemary, Cysteine Thiol*

ABSTRACT:

Lamiaceae herbs such as rosemary have excellent antioxidant

INTRODUCTION

The addition of antioxidants is one of the best ways to prevent the oxidative deterioration of foods. Therefore, the development of effective antioxidants, both artificial and natural, has been underway in recent years. However, these antioxidants are not always as effective when used in actual food products.¹ Of the many possible reasons for this, one is that foods are complex systems consisting of various ingredients. For example, effect varies in of emulsion-based foods depending on whether the antioxidant is in the aqueous or oil phase, as well as its presence at the interface, which can explain the so-called polar paradox phenomenon.² The coexistence of antioxidants is known to affect the total antioxidant capacity. The antioxidant effects of coexisting substances have been reported to add up in effects, however, synergistic and antagonistic effects have also been observed.^{3,4} To better understand the function of antioxidants, an analysis is necessary, assuming the influence of other components in food. If the resulting synergistic effects could enhance the function of existing antioxidants, technologies could in turn be developed to prevent the oxidative degradation of foods more effectively and for longer with the addition of smaller amounts.

Lamiaceae herbs, such as rosemary and sage, are known to have particularly strong antioxidant properties.⁵ This can be attributed to lipid-soluble abietane diterpenoid polyphenols, such as carnosol, as well as water-soluble rosmarinic acid. A lipidic rosemary extract, which contains carnosol and related diterpenes, has a high radical-scavenging antioxidant capacity, especially against lipid oxidation.⁶ Furthermore, it has been reported to have synergistic effects with other antioxidants,⁷ although the mechanism is not fully understood. Our recent research examines the interactions of carnosol and related diterpenoid polyphenols [carnosic acid (**CA**), carnosol (**CAR**), rosmanol (**ROS**), isorosmanol (**isoROS**), and epirosmanol (**epiROS**)] isolated from rosemary with other food components. The current paper reports the results of studies on the enhancement of the antioxidant function and its mechanism in the presence of a thiol compound as a model cysteine-containing food ingredient.

MATERIALS AND METHODS

Chemicals and Instruments. 2,2'-Azobis(2,4-

dimethylvaleronitrile) (AMVN) was purchased from FUJIFILM Wako (Osaka, Japan). Ethyl linoleate was purchased from Kanto Chemical (Tokyo, Japan) and utilized after purification using Florisil (FUJIFILM Wako) eluted with hexane.⁸ A mixture of ethyl linoleate hydroperoxide isomers was obtained through the air oxidation of ethyl linoleate according to the method described by Terao and Matsushita.⁹ *N*-Benzoylcysteine methyl ester (**BCysM**) and *N,N'*-dibenzoylcysteine dimethyl ester [(**BCysM**)²] were synthetically prepared using the previously reported method.¹⁰ The organic solvent extract of rosemary prepared of rosemary leaves was provided by Mitsubishi Chemicals (Yokohama, Japan). Carnosol (**CAR**) and carnosic acid (**CA**) as well as the quinone derivative of **CAR** (**CARQ**) were prepared according to the reported methods.^{11,12} All solvents and other reagents of extra pure or high-performance liquid chromatography (HPLC) grade were obtained from Nacalai Tesque (Kyoto, Japan). Nuclear magnetic resonance (NMR) spectra were recorded on a JNM-ECZ400S spectrometer (400 MHz; JEOL, Tokyo, Japan), while mass (MS) spectra were recorded on a JMS-T100 spectrometer (JEOL) using direct analysis in real-time (DART) and time-of-flight measurement modes. The molecular formulas of the compounds were obtained from high-resolution mass spectrometry (HR-MS) data using ChemCalc.¹³ Analytical HPLC was performed on the reaction products using a PU-2089 quaternary gradient pump (JASCO, Tokyo, Japan) equipped with an MD-2018 photodiode array detector (JASCO). The data were analyzed using ChromNAV software (ver.1.19.02, JASCO). The HPLC system used for lipid peroxide analysis consisted of an LC-10AD pump and an SPD-10Avp UV detector (Shimadzu, Kyoto, Japan). The obtained data were analyzed using ChromNavi Lite (v.2.04.00, JASCO). Preparative HPLC was performed using an LC-6AD pump (Shimadzu) equipped with an SPD-6A UV detector (Shimadzu). (Detailed information for analytical instruments and conditions can be found in section 1 of Supporting Information.)

Preparation of ROS, isoROS, and epiROS. A lipidic extract of rosemary (50 g) was subjected to octadecylsilyl silica gel (ODS) column chromatography (1 kg of Cosmosil 140C18-OPN, Nacalai Tesque) eluted step gradient from 50%, 60%, and 70% methanol in H₂O (2 L each) to obtain three fractions (0.46 g, 1.15 g, and 1.62 g) containing **isoROS**, **ROS**, and **epiROS**. These fractions were purified by HPLC using a Cosmosil 5C18-AR-II column (250 × 20 mm i.d.) and 1% acetic acid in

H₂O–CH₃CN (55:45, v/v) as the solvent (flow rate = 20 mL/min; detection wavelength = 284 nm) to yield pure **isoROS** (250 mg), **ROS** (630 mg), and **epiROS** (350 mg). The HR-MS and ¹H-NMR data of the isolated compounds were identical to those reported.^{14–16} (Analytical data for the structure identification can be found in section 2 of Supporting Information.)

Measurement of the antioxidant activity of rosemary polyphenols with and without thiol (BCysM). To 34 μL of ethyl linoleate in a 10 mL screw-capped tube (16 mm i.d. × 100 mm h), added 4 mM rosemary polyphenol in acetone (63 μL), 0.3 M AMVN in CH₃CN (100 μL), and 4 mM **BCysM** in acetone (0, 63, 126, or 189 μL) were successively added. The volume of the solution was adjusted to 2 mL with CH₃CN. The solution was then incubated at 37°C by shaking (100 min⁻¹) in the dark using a water-bath shaker. A 20 μL aliquot was removed from the solution at 1-h intervals, and diluted with 380 μL of methanol. Ten microliters of the diluted solution were injected into the HPLC system to analyze the ethyl linoleate hydroperoxides under the following conditions: column, YMC-ODS-A (150 × 4.6 mm i.d.) (YMC, Kyoto, Japan); solvent, CH₃CN–H₂O (9:1, v/v); flow rate, 1.0 mL/min; and detection, 234 nm (absorption wavelength of the diene moiety of hydroperoxides). The concentration of hydroperoxides was calculated from the peak area of *trans, trans*-2,4-hexadien-1-ol as the alternative compound using the following calibration equation. $y = 588,093x + 44,187$ ($R^2=0.99$), [y, peak area at 234 nm; x, amount (nmol) of *trans, trans*-2,4-hexadien-1-ol (range, 0.1–10 nmol)]

Analysis of the reaction products from CAR in the antioxidant reaction with and without thiol (BCysM). The reaction solution of **CAR** with and without **BCysM** (one molar equivalent), were prepared using the same procedure described above. At the same intervals, an additional 10 μL aliquot was removed from the reaction solution and injected into the HPLC system to analyze the reaction products using the following conditions: column, Cosmosil 5C18-AR-II (250 × 4.6 mm i.d., Nacalai Tesque); solvent A, acetic acid–H₂O (1:100, v/v); solvent B, CH₃OH; gradient conditions, B% (time) = 60% (0 min), 100% (40 min), and 100% (40–50 min); flow rate, 0.5 mL/min; and detection, 245 and 284 nm. The concentration of observed compound was calculated from the peak area using the following calibration equations: **BCysM**: $y = 486,771x + 192,287$ ($R^2=0.99$), [y, peak area at 245 nm; x, amount (nmol)

(range, 0.1–50 nmol)]; **(BCysM)²**: $y = 1,097,523x + 9,631$ ($R^2=1.00$), [y, peak area at 245 nm; x, amount (nmol) (range, 0.1–10 nmol)]; **CAR**: $y = 193,581x + 6,367$ ($R^2=0.99$), [y, peak area at 284 nm; x, amount (nmol) (range, 0.1–50 nmol)]; **CARQ**: $y = 81,197x - 12,429$ ($R^2=1.00$), [y, peak area at 284 nm; x, amount (nmol) (range, 0.1–10 nmol)].

Analysis of the reaction products of CARQ and BCysM. To 1.8 mL CH₃CN, 63 μL of **CARQ** in CH₃CN (20 mM) and 63 μL of **BCysM** (20 mM) were added. The solution was stirred well, and 10 μL of aliquot was immediately taken from the solution and analyzed by HPLC under the following conditions: column, Cosmosil 5C18-AR-II (250 × 4.6 mm i.d., Nacalai Tesque); solvent A, acetic acid–H₂O (1:100, v/v); solvent B, CH₃OH; gradient conditions, B% (time) = 60% (0 min), 100% (40 min), and 100% (40–50 min); flow rate, 0.5 mL/min; detection, 245 and 284 nm. The solution was then incubated at 35°C for 2 h, and additional aliquots were taken 1 and 2 h later and analyzed under the same conditions. The concentrations of **CARQ**, **CAR**, **BCysM**, and **(BCysM)²** were determined using the corresponding calibration equations. New products **1** and **2** were quantitatively analyzed using the following calibration equations: **1**: $y = 730,972x - 287,348$ ($R^2=0.99$), [y, peak area at 245 nm; x, amount of **1** (nmol) (range, 0.1–20 nmol)]; **2**: $y = 722,504x + 8,203$ ($R^2=1.00$), [y, peak area at 245 nm; x, amount of **2** (nmol) (range, 0.1–20 nmol)].

Preparation and structural determination of compounds 1 and 2. CH₃CN solutions (33 mL) of **CARQ** (20 mM) and **BCysM** (20 mM) were mixed well and incubated for 3 h at 37°C. The solution was evaporated to dryness, and the residue was purified by preparative HPLC [column, COSMOSIL 5C18-AR-II (250 × 20 mm i.d.); solvent, acetic acid–H₂O–CH₃OH (1:30:70, v/v/v); flow rate: 10 mL/min; detection: 245 nm] to obtain **1** (25 mg) and **2** (20 mg). (Analytical data for the structure determination of **1** and **2** can be found in section 2 of Supporting Information.)

Density functional theory (DFT) calculations. The 3D structures for the calculations were created using Avogadro (v.1.2.0)¹⁷ and pre-optimized using molecular mechanics with the MMFF94 field from predicted stable conformers. The Gaussian (R)16 package (v.1.1; Hulinks, Tokyo, Japan)¹⁸ was used to optimize the stereostructures and calculate the energies and natural charges of the compounds. The B3LYP method, 6-311+G(d, p) basis set, and solvation model density (SMD)¹⁹ (solvent,

CH₃CN) implemented in the package were used for the calculations. (Detailed conditions for the DFT calculation can be found in section 3 of Supporting Information.)

RESULTS AND DISCUSSION

Antioxidant activity of rosemary polyphenols in the presence and absence of cysteine thiol, BCysM. The antioxidant activity of five types of rosemary polyphenols (**CA**, **CAR**, **ROS**, **epiROS**, and **isoROS**; see structures in Figure 1) was assessed by inhibiting the formation of hydroperoxides from ethyl linoleate. All polyphenols, at a concentration of 0.125 mM, showed potent antioxidant activity for up to 1 h against lipid oxidation induced by AMVN (15 mM). In contrast, the cysteine thiol **BCysM**, at the same concentration, did not display any antioxidant activity, as shown in Figure 2. Figure 2 further shows the antioxidant activity of the polyphenols with one molar equivalent of **BCysM**, revealing that only **CAR** and **isoROS** have a longer antioxidant effect in the presence of the thiol. The potent antioxidant functions of thiol compounds such as glutathione and *N*-acetylcysteine are well recognized in biological systems,²¹ and their effective antioxidant activity has been observed in various assay systems, however, their efficacy depends on the radical species used, the measurement system, and other conditions.²² In 2014, we discovered that *N*-acylcysteine esters do not exhibit antioxidant properties against lipid oxidation but cysteine derivatives with free α -amino or carboxylate groups strongly inhibit AMVN-induced linoleic acid oxidation, because of the formation of an active thiolate anion by an intramolecular proton shift to α -amino or carboxylate.²³ Comparing bond dissociation enthalpy (BDE) of S-H (ca. 86 kcal/mol) in *N*-acylcysteine esters²⁴ to that of hydroperoxides (OO-H, ca. 88 kcal/mol)²⁵ indicated that the thiol group of **BCysM** cannot exhibit effective antioxidant activity through lipid peroxy radical trapping, but rather that degradation began with the withdrawal of a hydrogen atom at α -position with lower BDE (ca. 80 kcal/mol).²⁴ Thiols are also known to have high nucleophilicity and can be easily conjugate-added to carbonyl compounds. Orthoquinones are antioxidant reaction products of catechol-type polyphenols and are targets of the conjugate addition of thiols as carbonyl compounds. As a result, the phenolic hydroxy group, which is essential for antioxidant activity, is restored by the reaction. It is well known that two phenolic hydroxy groups in an ortho relationship exhibit strong

antioxidant activity.²⁶ Several phenolic acids and flavonoids have been reported to exhibit longer antioxidant effect by this mechanism.²⁷⁻³⁰ Figure 3 shows the results of measuring the enhancement of the antioxidant properties of **CAR** and **isoROS** by different amounts of coexisting **BCysM**; the antioxidant effect lasted longer with the amount of thiol added in both cases. Considering the structures of **CAR**- and **isoROS**-derived quinones (**CARQ** and **isoROSQ** respectively), the conjugate addition reaction of **BCysM** is only possible at one site at the 14-position. Therefore, for these diterpenoid polyphenols, other mechanisms for enhancing the antioxidant effect should be considered besides the thiol addition mechanism described.

Catalytic antioxidant properties of CAR and isoROS in the presence of BCysM. **CAR** was used to elucidate the mechanism of the antioxidant reaction in the presence of **BCysM**. Figure 4 shows the results of the HPLC analysis of the antioxidant reaction products from **CAR** in the presence of one molar equivalent of **BCysM** as well as the analytical data at the beginning of the reaction. At the beginning of the reaction, the peaks of **CAR** and **BCysM** were observed at retention times 28.3 and 9.7 min respectively. During the 4-h reaction, **BCysM** decreased by 87%, while **CAR** decreased by only 22%. Three new peaks were observed at retention times 14.6, 29.8, and 31.0 min. The peak at 14.6 min was attributed to the cystine derivative (**BCysM**)² (a dimer of **BCysM** through SS linkage) based on a comparison with the retention time of the synthetically obtained sample. Figure 5 shows the time-course change of the compounds at the peaks detected in the antioxidant reaction of **CAR** (0.63 mM) with or without **BCysM** (0.63 and 1.26 mM). Under the conditions employed (AMVN, 15 mM; ethyl linoleate, 50 mM; solvent, CH₃CN; and reaction temperature, 37°C), **CAR** decreased linearly by 68% in 4 h. However, under the same conditions, **BCysM** decreased by 44%, as shown in panels C and D respectively in Figure 5. Note that this concentration of **BCysM** did not show antioxidant activity, whereas **CAR** showed strong activity (data not shown) and produced the same amount of quinone **CARQ**. In the presence of both **CAR** and **BCysM**, the rate of decrease in **CAR** was smaller, whereas that in **BCysM** was greater. Furthermore, a small amount of **CARQ** was produced, while (**BCysM**)² and new compounds **1** and **2** accumulated as the reaction progressed (Figure 5, panel A). This trend was even more pronounced in the reaction of **CAR** with two molar equivalents of **BCysM**, as shown in Figure 5,

panel B. The reaction products in the radical scavenging-antioxidation of catechol-type polyphenols are orthoquinone derivatives.^{11,31} The oxidative reactivity of **CARQ** was considered to convert **BCysM** to disulfide (**BCysM**)². Figure 6 shows the results of HPLC analysis of the reaction products from the mixture of **CARQ** and equimolar **BCysM** and from **CARQ** alone and **BCysM** alone, under the same analytical conditions. The reaction results showed that **CAR** and (**BCysM**)² were formed immediately after mixing **CARQ** and **BCysM**, as shown in the time course data on the right side of Figure 6. These results suggest that **CARQ**, the product of the antioxidant reaction of **CAR**, is quickly reduced by **BCysM** to restore **CAR** and reexhibits antioxidant activity. In conclusion, **CAR** should be recognized as a catalytic antioxidant since it exhibited excellent antioxidant properties in the presence of thiols in this study. **IsoROS**, which showed similar antioxidant properties, could be another catalytic antioxidant. Antioxidant catalysts have been examined by several studies. They are mimics of the catalytic sites of redox enzymes³² or synthetic compounds containing heavy chalcogen atoms with high redox reactivity.³³ This study is the first to report the catalytic antioxidant activity of diterpenoid polyphenols **CAR** and **isoROS**, but not of **CA**, **ROS**, and **epiROS**.

The addition products of BCysM to CARQ. Thiols have high nucleophilic activity and can undergo conjugate addition to quinones. This addition reaction is another mechanism whereby the antioxidant activity of polyphenols can be enhanced by restoring the 1,2-diphenol structure.^{28,29,34} In the reaction of **CARQ** with **BCysM**, the same products **1** and **2** from the antioxidant reaction of **CAR** were detected, as shown in Figures 4 and 6. Compounds **1** and **2** were successfully isolated from the reaction mixture of **CARQ** and **BCysM**. The HR-MS data of **2** revealed its molecular formula to be C₃₁H₃₇NO₇S (*m/z* 566.2198 [M-H]). The ¹H-NMR data of **2** showed signal sets similar to those of **CAR** and **BCysM**, but did not show signals corresponding to the proton at the 14-position of **CAR** and the thiol group of **BCysM**. These data revealed that **2** was a coupling product of **CAR** and **BCysM** between the 14-position of **CAR** and the thiol group of **BCysM**, as shown as structure 2 in Figure 7. The molecular formula of compound **1** was estimated to be C₃₁H₃₅NO₇S from its HR-MS data (*m/z* 564.2042 [M-H]). ¹H-NMR data of **1** showed similar data to those of **2**, indicating the same coupling structure with **CAR** and **BCysM**. However, two protons were missing from the proton

set owing to **BCysM**, and a low-field-shifted olefinic proton was observed at 7.14 ppm. These data indicated that **1** was an oxidized compound at the 1',2'-positions of the **BCysM** part. The stereostructure of the olefin was determined to be *Z* by observing the nuclear Overhauser effect (NOE) from 3'-OCH₃ to H-1'. Thus, the structure of **1** was determined to be a dehydrocysteine-substituted **CAR** as shown in Figure 7. Both compounds were addition products of the thiol to the 14-position of **CARQ** and have restored diphenol groups, which again exhibit antioxidant activity. Although the reason for the production of oxidized product **1** is unclear, radical oxidation may occur at the α-position of **BCysM**, where the bond dissociation enthalpy of the carbon-proton bond is lowest, producing a 1,2-dehydro derivative of **BCysM**, which may act as another nucleophilic thiol.

Prediction of the reaction mechanisms of rosemary polyphenol quinones with BCysM based on DFT calculations. Quinones are known to have both oxidative and electrophilic addition reactivities, and thiols have reductive and nucleophilic addition reactivities, which shape their functional expression in foods and living cells.³⁵ Regardless of the type of reactions, both reactivities of substituted quinones generally increase with the electron-withdrawing capacity of the substituent groups.^{36,37} In the studied polyphenols, the only differing substituent attached to the quinone structure is the alkyl group adjacent to the 8-position. Specifically, **CA** has a simple methylene group, **ROS** and **epiROS** have a hydroxymethylene group, and **CAR** and **isoCAR** have an acyloxymethylene group, as shown in Figure 1. The most electron-withdrawing group is the acyloxymethylene group, which explains the high reactivity of the quinone derivatives of **CAR** and **isoROS** (**CARQ** and **isoROSQ** respectively) with the thiol compound **BCysM**. These considerations, based on the electronic theory of classical organic chemistry, were confirmed by *ab initio* calculations. Table 1 shows the DFT calculation results for the following redox reaction between **BCysM** and the quinone derivatives of rosemary polyphenols.

Polyphenol quinone + 2 **BCysM** ⇌ Polyphenol + (**BCysM**)²

(Optimized stereostructures resulting from the calculations are shown in Figure S1 in section 3 of Supporting Information.).

Compared with other polyphenol quinones, the larger negative values (−7.405 and −6.338 kcal/mol respectively) of the calculated Gibbs free energy change (ΔG) in the reactions of **isoROSQ** and **CARQ** indicate

that the reactions yield the products more efficiently. Although a comparison of transition states is necessary to accurately determine reaction rates, if the Bell-Evans-Polanyi principle³⁸ or Marcus theory³⁹ can be adapted, the high negative ΔG values of the reactions from **isoROSQ** and **CARQ** would suggest that these reactions occurred more rapidly.

Quinones have multiple reaction positions for nucleophilic addition and have a high potential for redox reactions, therefore, the predicting the reaction mechanism is challenging. Although many methods have been developed to predict reactive positions,⁴⁰ in this study, the most reactive position of **CARQ** and predicted intermediates was selected based on the condensed Fukui function, easily obtained by the natural population analysis of DFT calculations.⁴¹ The indices for the condensed Fukui functions were obtained using UCA-FUKUI software.⁴² The values for the atoms of orthoquinone moieties of **CARQ** and its reaction intermediates are summarized in Table 2. Regarding the prediction of the reaction mechanism shown in Figure 8, the 8-position ($f^+ = 0.216$) is the most reactive site for the nucleophilic attack on **CARQ**, where **BCysM** reacts nucleophilically to form intermediate **3**. Although the 14-position is the third most reactive position of **3** for nucleophilic attack ($f^+ = 0.139$), the electrophilic reactivity of S at the 8-position is predominant ($f^- = 0.335$) in comparison with other positions. Therefore, intramolecular cyclization may occur to yield **4**. The thiol anion produced in the reaction thus far makes a nucleophilic attack on the thiirane S atom ($f^+ = 0.589$) at the 8- and 14-positions, resulting in the formation of **CAR** and disulfide (**BCysM**)². Reacting at the second reactive 14-position ($f^+ = 0.107$) of **4**, the thiirane ring is opened by the attack of the thiol anion (RS⁻), and the aromaticity is restored by the elimination of one mole of the thiol to yield product **2**. Radical reactions between thiols and quinones have been reported.⁴³ A radical mechanism can be proposed using the Fukui function (f^0) as an indicator for this reaction (Figure S2 and Table S7 in section 3 of Supporting Information). It is important to note that a one-electron transfer reaction from thiol to quinone is required in the absence of exogenous radical species. However, based on the calculated ionization potential (Adiabatic IP = 149.8 kcal/mol for **BCysM**) and electron affinity (Adiabatic EA = 92.5 kcal/mol for **CARQ**), initiating a one-

electron transfer reaction between both starting materials might be less progressive than the nucleophilic addition of thiols.

In conclusion, **CAR** and **isoROS** in rosemary diterpenoid polyphenols showed catalytic antioxidant activity in the presence of thiols. This mechanism allows **CAR** and **isoROS** to continuously exhibit antioxidant properties in the presence of thiol-containing substances as long as thiols are present. Antioxidant activity depends on the physicochemical properties of the antioxidant used. The use of catalytic antioxidants is advantageous in that their superior properties are continuously maintained during food storage. Further, two quinone derivatives, the antioxidant products of **CAR** and **isoROS**, were found to efficiently convert thiols to disulfides. Quinone substances are well known to be toxic to living organisms. This toxicity is attributed to the irreversible binding of quinones to biomaterials including protein thiol.⁴⁴ Therefore, the mechanism of thiol addition to quinones has been extensively studied.⁴³ On the other hand, the mechanism of disulfide formation by quinones is complex and not yet fully understood.⁴⁵ Importantly, this reaction has the advantage of yielding only the original polyphenol and disulfide without producing toxic substances. In this study, an organic solvent was used as the reaction medium. However, since many foods are complex systems containing water, future research should be conducted using actual food systems. If similar results are obtained in the future studies, **CAR** and **isoROS** can act as highly effective food antioxidants and selectively form disulfide bonds through their catalytic antioxidant action. This is expected to contribute to the improvement of food texture since disulfide bonds are essential for protein cross-linking and are known to improve the physical properties of foods, such as the dough formation of flour⁴⁶ and the gelatinization of meat proteins.⁴⁷

Table 1. Calculated Gibbs Free Energy Change (ΔG) of the Reaction of Rosemary Polyphenol Quinones and BCysM.

Compound (Polyphenol Quinone)	ΔG (kcal/mol)
isoROSQ	-7.405
CARQ	-6.338
epiROSQ	-4.895
ROSQ	-4.518
CAQ	-2.824

ΔG was calculated by the equation: $\Delta G = [G(\text{Polyphenol}) + G(\text{BCysM}^2)] - [G(\text{Quinone}) + G(\text{BCysM}) \times 2]$. G is Gibbs free energy calculated by DFT method using B3LYP functional, 6-311+G(d,p) basis set, and SMD solvation model (CH₃CN).

Table 2. Condensed Fukui Indices of the Atoms in Quinone Moieties of CARQ and Its Predicted Intermediates for Nucleophilic (f^+) and Electrophilic (f^-) Attacks.

Atom position	CARQ	3		4
	f^+	f^+	f^-	f^+
C-8	0.216	-0.046	0.013	-0.108
C-9	-0.014	0.136	0.055	0.001
C-11	0.128	-0.008	0.074	0.023
C-12	0.139	0.207	-0.027	0.052
C-13	0.041	0.017	0.092	0.001
C-14	0.046	0.139	0.031	0.107
11-C-O	0.156	0.029	0.069	0.000
12-C-O	0.156	0.170	0.027	0.023
8-C-S	-	0.130	0.335	0.589
or				
8,14-C-S				

The Fukui index (f^+ for nucleophilic attack and f^- for electrophilic attack) values were obtained using UCA-FUKUI software through the finite difference approximation using the natural charges of

corresponding atoms, which were obtained by DFT calculations. Bold number in each column indicates the largest Fukui index value.

Methyl mercaptan (CH₃SH) was used as the thiol for DFT calculations instead of BCysM.

Figure 1. Chemical structures of five rosemary polyphenols and *N*-benzylcysteine methyl ester (BCysM).

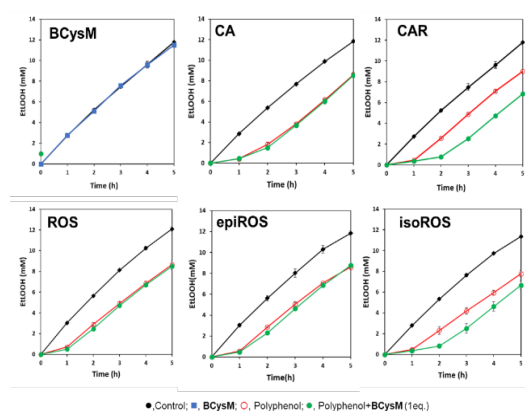

Figure 2. Antioxidant activity of rosemary polyphenols in the presence or absent of BCysM.

Reaction conditions: Ethyl linoleate, 50 mM; AMVNN, 15 mM; Polyphenols, 0.125 mM; and BCysM, 0.125 mM in CH₃CN at 37°C. Data are presented by mean ± SE (n = 2).

Figure 3. Concentration effects of BCysM on antioxidant activity of CAR and isoROS.

Reaction conditions: Ethyl linoleate, 50 mM; AMVN, 15 mM; Polyphenols, 0.125 mM; and BCysM, 0.125–0.375 mM in CH₃CN at 37°C. Data are presented by mean ± SE (n = 2).

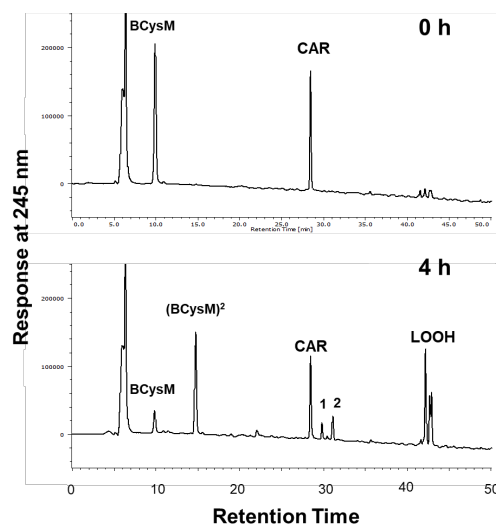

Figure 4. HPLC analytical results of antioxidant reaction solutions of CAR in the presence of BCysM.

Reaction conditions: Ethyl linoleate, 50 mM; AMVN, 15 mM; CAR, 0.63 mM; and BCysM, 0.63 mM in CH₃CN at 37°C. Analytical conditions: column, Cosmosil 5C18-AR-II (250 × 4.6 mm i.d); solvent A, acetic acid–H₂O (1:100, v/v); solvent B, CH₃OH; gradient conditions, B% (time) = 60% (0 min), 100% (40 min), 100% (40–50 min); and flow rate, 0.5 mL/min.

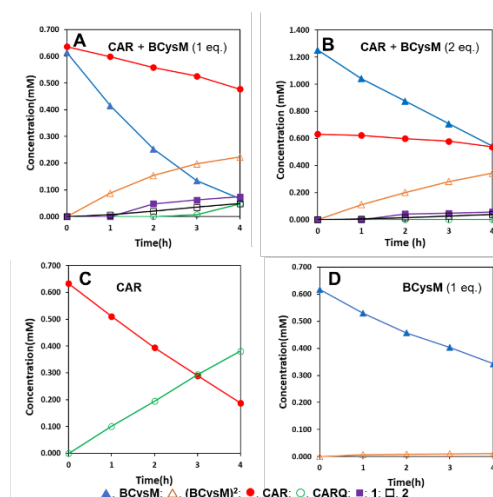

Figure 5. Quantitative time-course data for CAR, CARQ, BCysM, (BCysM)², and compounds 1 and 2 in antioxidant reaction solutions.

Panel A: Reaction of CAR (0.63 mM) and BCysM (0.63 mM); Panel B: Reaction of CAR (0.63 mM) and BCysM (1.26 mM); Panel C:

Reaction of **CAR** (0.63 mM); Panel D: Reaction of **BCysM** (0.63 mM).
 Other reaction conditions: Ethyl linoleate, 50 mM; AMVN, 15 mM in CH_3CN at 37°C .

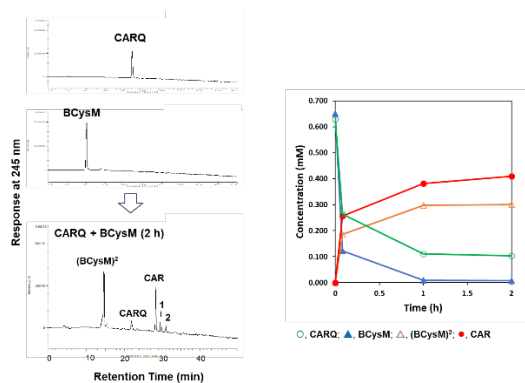

Figure 6. HPLC analysis data for **CARQ**, **BCysM** and a reaction mixture of **CARQ** and **BCysM**, and time-course data for the reaction mixture.

Reaction conditions: 0.63 mM **CARQ** and 0.63 mM **BCysM** in CH_3CN at 37°C

Analytical conditions: column, Cosmosil 5C18-AR-II (250×4.6 mm i.d); solvent A, acetic acid– H_2O (1:100, v/v); solvent B, CH_3OH ; gradient conditions, B% (time) = 60% (0 min), 100% (40 min), and 100% (40–50 min); and flow rate, 0.5 mL/min.

Figure 7. Chemical structures of compounds **1** and **2**.

Position numbers were tentatively assigned based on those of abietane diterpenoids.

Figure 8. Reaction mechanisms of **CARQ** and thiol based on the condensed Fukui indices.
